Properties of HDFS as a storage medium:

- Distributed
- Partitioned
- Fault-Tolerant by using replication
- Write-once, read-many
- Commodity Hardware
- File stored as blocks
- Designed for high latency, high throughput batch processing.

## HDFS Architecture

- Master/Slave
- Master: **NameNode**
- Slaves: **DataNodes**
- NameNode takes care of metadata (not actual data) storage, and resource management
- DataNodes store actual data in units called **blocks**.  
In Hadoop 2, default block size = 128 MB
- Locality of computation - computation is scheduled where data is located, so there is less data movement.

See

[https://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/HdfsDesign.html#HDFS\\_Architecture](https://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/HdfsDesign.html#HDFS_Architecture) for details

Machine  
Learning

Read the details below about block size. Note that a file of size 129 MB would occupy two blocks - one of size 128 MB, and second one of size 1 MB and not 128 MB

HDFS, too, has the concept of a block, but it is a much larger unit—128 MB by default. Like in a filesystem for a single disk, files in HDFS are broken into block-sized chunks, which are stored as independent units. Unlike a filesystem for a single disk, a file in HDFS that is smaller than a single block does not occupy a full block's worth of underlying storage. (For example, a 1 MB file stored with a block size of 128 MB uses 1 MB of disk space, not 128 MB.) When unqualified, the term “block” in this book refers to a block in HDFS.

## Why are block sizes in HDFS so large? Read below

### WHY IS A BLOCK IN HDFS SO LARGE?

HDFS blocks are large compared to disk blocks, and the reason is to minimize the cost of seeks. If the block is large enough, the time it takes to transfer the data from the disk can be significantly longer than the time to seek to the start of the block. Thus, transferring a large file made of multiple blocks operates at the disk transfer rate.

A quick calculation shows that if the seek time is around 10 ms and the transfer rate is 100 MB/s, to make the seek time 1% of the transfer time, we need to make the block size around 100 MB. The default is actually 128 MB, although many HDFS installations use larger block sizes. This figure will continue to be revised upward as transfer speeds grow with new generations of disk drives.

This argument shouldn't be taken too far, however. Map tasks in MapReduce normally operate on one block at a time, so if you have too few tasks (fewer than nodes in the cluster), your jobs will run slower than they could otherwise.

## Important features of Apache Spark project<sup>1</sup>:

- Open-source cluster computing framework
- Developed to provide real-time, low latency queries on data that is stored in a cluster, such as Hadoop
- Uses partitioned, and distributed in-memory datasets, known as **Resilient Distributed Datasets (RDD)** to speed up computation.
- Disk I/O, which is the limiting factor in case of traditional MapReduce algorithms, is avoided by using RDDs
- Runs programs up to 100x faster than Hadoop MapReduce in memory, or 10x faster on disk.

Suppose you have a file "movies.csv" :

```
movieId,title,genres
1,Toy Story (1995),Adventure|Animation|Children|Comedy|Fantasy
2,Jumanji (1995),Adventure|Children|Fantasy
3,Grumpier Old Men (1995),Comedy|Romance
4,Waiting to Exhale (1995),Comedy|Drama|Romance
5,Father of the Bride Part II (1995),Comedy
6,Heat (1995),Action|Crime|Thriller
7,Sabrina (1995),Comedy|Romance
8,Tom and Huck (1995),Adventure|Children
9,Sudden Death (1995),Action
```

Which of the following is the correct way to load this file into a DataFrame?

- 1 `movies = spark.read.option("header", "true").csv("movies.csv")`
- 2 `movies = spark.read.option("header", "false").csv("movies.csv")`
- 3 `movies = spark.textFile.csv("movies.csv")`
- 4 `movies = spark.csv("movies.csv")`

Suppose you have a file "ratings.csv", which you have loaded into a **Dataframe** called **ratings**

```
userId,movieId,rating,timestamp  
1,31,2.5,1260759144  
1,1029,3.0,1260759179  
1,1061,3.0,1260759182  
1,1129,2.0,1260759185  
1,1172,4.0,1260759205  
1,1263,2.0,1260759151
```

How can you find out the number of ratings for each movieId?

- 1 ratings.reduceByKey("movieId").count()
- 2 ratings.groupBy("movieId").count()
- 3 ratings.groupBy("movieId").keys
- 4 ratings.groupBy("movieId").keys.count()

You have loaded the files below into DataFrames **movies** and **ratings**

```
movieId,title,genres
1,Toy Story (1995),Adventure|Animation|Children|Comedy|Fantasy
2,Jumanji (1995),Adventure|Children|Fantasy
3,Grumpier Old Men (1995),Comedy|Romance
4,Waiting to Exhale (1995),Comedy|Drama|Romance
5,Father of the Bride Part II (1995),Comedy
6,Heat (1995),Action|Crime|Thriller
7,Sabrina (1995),Comedy|Romance
8,Tom and Huck (1995),Adventure|Children
9,Sudden Death (1995),Action
```

```
userId,movieId,rating,timestamp
1,31,2.5,1260759144
1,1029,3.0,1260759179
1,1061,3.0,1260759182
1,1129,2.0,1260759185
1,1172,4.0,1260759205
1,1263,2.0,1260759151
```

How would you join these two Dataframes? <sup>4</sup>

- 1 `movies.join(ratings, movies.col("movieId") == ratings.col("movieId"))`
- 2 `movies.join(ratings, movies.col("movieId") === ratings.col("movieId"))`
- 3 `movies.join(ratings)`
- 4 `ratings.join(movies)`

You have loaded the files below into DataFrames **movies** and **ratings**

movieId,title,genres	userId,movieId,rating,timestamp
1,Toy Story (1995),Adventure Animation Children Comedy Fantasy	1,31,2.5,1260759144
2,Jumanji (1995),Adventure Children Fantasy	1,1029,3.0,1260759179
3,Grumpier Old Men (1995),Comedy Romance	1,1061,3.0,1260759182
4,Waiting to Exhale (1995),Comedy Drama Romance	1,1129,2.0,1260759185
5,Father of the Bride Part II (1995),Comedy	1,1172,4.0,1260759205
6,Heat (1995),Action Crime Thriller	1,1263,2.0,1260759151
7,Sabrina (1995),Comedy Romance	
8,Tom and Huck (1995),Adventure Children	
9,Sudden Death (1995),Action	

You would like to find the **names** of the **top 5 highest rated movies**. Which of the following approaches would be **most efficient**?

- 1 First join both Dataframes, compute avg for each movies, then sort by avg in descending order, and finally filter to top 5 rows.
- 2 First compute the avg for each movie, sort by avg in descending order and filter to top 5 rows, then join the filtered Dataframe to the movies DataFrame

val train = spark.read.csv("train.csv")
val lr = new LogisticRegression().setMaxIter(10)
lr.setRegParam(0.3).setElasticNetParam(0.8)
```

Which of the following can be used to train the **lr** algorithm on the **train** dataset and obtain a trained model?

- 1 lr.train(train)
- 2 lr.fit(train)
- 3 lr.doTheTraining(train)
- 4 train.fit(lr)

You would like to perform Logistic Regression on a dataset and use the code below:

```
val train = spark.read.csv("train.csv")
val lr = new LogisticRegression().setMaxIter(10)
    ~~~~~lr.setRegParam(0.3).setElasticNetParam(0.8)
# lr is trained on the train dataset to obtain model object
val test = spark.read("test.csv")
```

Which of the following can be used to test the lr model **model** on the **test** dataset?

- 1 model.transform(test)
- 2 model.fit(test)
- 3 model.doTheTesting(test)
- 4 test.fit(model)

You have a dataset containing 1 million rows of data, which you would like to put into 10 groups such that items in each group are similar to each other and dissimilar to other groups. Which algorithm can help you accomplish this?

- 1 K-means
- 2 Decision Tree
- 3 Logistic Regression
- 4 Linear Regression
